# COS110 - Program Design: Introduction

## Practical 7 Specifications:
## Linked Lists

Release Date: 10-10-2022 at 06:00

Due Date: 14-10-2022 at 23:59

Total Marks: 110

# Contents

# 1 General instructions

- This practical should be completed individually, no group effort is allowed.
- You may not include/import any other modules than what were already included in the given files
- If your code does not compile you will be awarded a mark of zero. Only the output of your program will be considered for marks.
- You are not allowed to plagiarise.
- You will be afforded 10 upload opportunities.

# 2 Plagiarism

The Department of Computer Science considers plagiarism as a serious offence. Disciplinary action will be taken against students who commit plagiarism. Plagiarism includes copying someone else's work without consent, copying a friend's work (even with consent) and copying material (such as text or program code) from the Internet. Copying will not be tolerated in this course. For a formal definition of plagiarism, the student is referred to `https://www.up.ac.za/students/article/2745913/what-is-plagiarism`. **If you have any form of question regarding this, please ask one of the lecturers, to avoid any misunderstanding.** Also note that the OOP principle of code re-use does not mean that you should copy and adapt code to suit your solution.

# 3 Introduction

## 3.1 Scenario

For this practical you will take the role of a backend developer at an IT company. You were given a ticket to implement a calendar interpretation system from the data returned by the remote API. The data you receive from the API is read and sent to you as a vector of data. You will need to interpret the data as events and store it in an easy-to-use way for the front-end developers.
After some thought, you decided that implementing a linked list to store and manage the events would be best because of how easy it is to insert and remove data randomly within it. You also decide that sorting the data according to the start time would be better for the sake of efficiency.

Since you are an experienced developer you also decide to use some code from an old project as a library to make development of this system a bit easier(Utils.h).

## 3.2 Valgrind

As a software developer it is your job to ensure you write code that is both efficient and memory safe. Especially since it is meant to be used on a hosted server and memory could be fatal for the system. Thus for this practical your submission will be tested for memory leaks. An easy way to check if your program has memory leaks is with a tool called Valgrind. For Linux users you would need to run the following command to install valgrind:
**sudo apt-get install valgrind**
Then you need to edit your makefile run command to run with valgrind instead of the plain run. To do this you can simply change your run command to execute through valgrind instead. To do this you will replace need to **"./compiledfile"** with **"valgrind –leak-check=full ./compiledfile"** If you have a memory leak, valgrind will print a leak summary that will look something like:

```
LEAK SUMMARY:
definitely lost: 48 bytes in 1 blocks
indirectly lost: 0 bytes in 0 blocks
```

If you do have memory leaks you are not deleting memory that you have allocated.

## 3.3 Mark Distribution

| Activity | Testing | Mark Possible |
|---|---|---|
| Task 1 | Utils | 5 |
| Task 2 | Event | 24 |
| Task 3 | Calendar | 80 |
| Task 4 | Valgrind | 1 |
| Total | | 110 |

# 4 Your Tasks

A linked list is a basic and very dynamic data structure that is used to implement other data structures such as Binary Trees and Skip Lists. Your task will be to implement your own version of a linked list data structure. In your implementation, an "Event" is a node inside your linked list and "Calendar" is your linked list manager class.

The linked list data structure makes use of storing objects on the heap that point to each other. In your case, you will have "Event" nodes on the heap pointing to other nodes on the heap. It's best to think about a linked list as a graph-like structure, where nodes can point to each other. The "Calendar" class will store the first (head) node that will point to the next node and that one will point to the next and so on and so forth until we reach a node that points to NULL. Which would be the end of the linked list. By default, the head is set to NULL to indicate that the list is empty.

For this practical you will be given:

- Utils.h
- Calendar.h
- Calendar.cpp
- Event.h
- Event.cpp

You will be coding inside every file given. You are also required to write your own testing file to ensure your code is working.

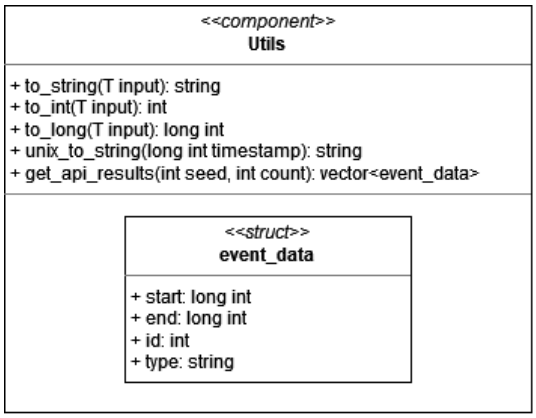
During development you decided it would be best to mock the api data for easier development. Thus the function "get_api_results" will generate random api results for you to work with.

## 4.1 Unix Time Explained

The unix time stamp is a simple way for computers to track time. Using a long integer they count every second since 1970 Jan 1st. For example the time "2022/10/1 12:30:30" would be expressed as the integer "1664620230". To more experiment with this standard you may use the site: `https://www.unixtimestamp.com/`

## 4.2 Task 1

### 4.2.1 Utils.h

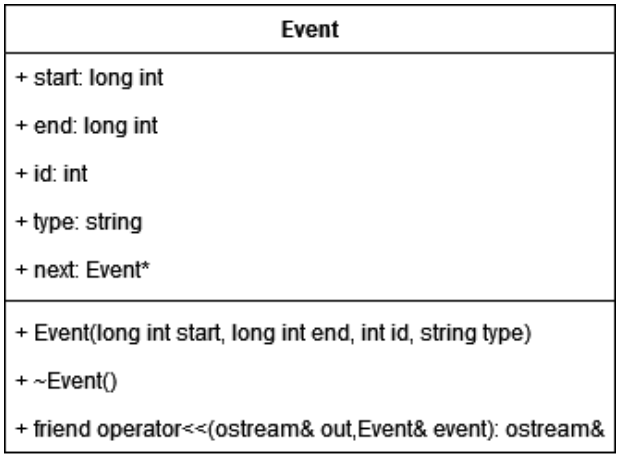


First you will need to implement the general to_string(T input), to_int(T input) and to_long(T input) functions inside the **"Utils.h"** file. **Note that Utils is not a class. It is a collection of static functions and a event_data struct.**

- **static string to_string(T input)**
  This function is a template function that places the given input into a stringstream object and returns the string by calling the str() function of the stringstream object.
- **static int to_int(T input)**
  This function is a template function that places the given input into a stringstream object and returns an integer by placing it into a temporary integer variable and returning the temporary variable.
- **static int long to_long(T input)**
  This function is a template function that places the given input into a stringstream object and returns a long int by placing it into a temporary long integer variable and returning the temporary variable.
- **static string unix_to_string(long int timestamp)**
  This function is a given function that will convert a given unix timestamp into a readable string.
- **static vector<event_data> get_api_results(int seed, int count)**
  This function is a given function that will generate a vector of event data to mock the api call during development.
  Note: The random values generated will differ from platform to platform due to the way each platform calculates a random value.

## 4.3 Task 2

### 4.3.1 Event



The Event class will act as both the node in our linked list and the data holder. Every event object will store data within itself as well as a pointer to the next item and previous item in the linked list.

- **Event(long int start,long int end,int id,string type)**
  The constructor for the Event class will take 4 parameters. It will need to set its own values equal to the values passed. The values passed are in order: long int start, long int end, int id and string type.
  Your constructor must also set the next pointer to NULL.

- **~Event()**
  The destructor will not do anything as it does not have any memory stored on the heap excluding itself.

- **friend ostream operator«(ostream out,Event event)**
  The overloaded « operator will need to place the events type as well as the string of the start and end.
  It must first print the type then a space, then the unix_to_string() of start followed by a "->" then lastly the unix_to_string() of end.**DO NOT ADD A NEWLINE AT THE END**
  So the formatting should be:

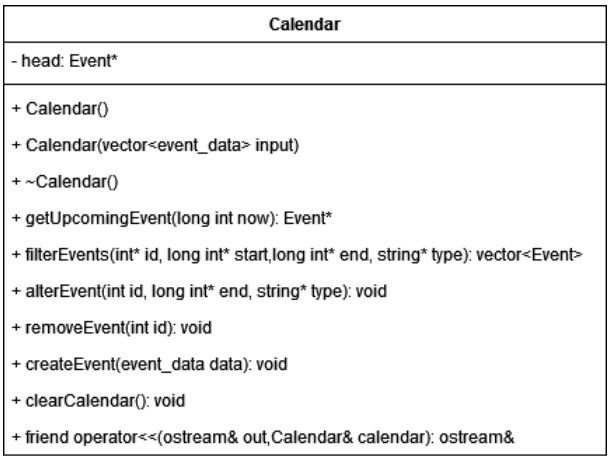
```
Type unix_to_string(Start)->unix_to_string(End)
```

  Example of data filled in:

```
Class Test 2025/08/29 01:17:34->2025/12/19 15:29:53
```

## 4.4 Task 3

### 4.4.1 Calendar



The Calendar class the manager for our linked list. It manages our linked and retrieves/alter data within our list. Since this is a link list the Calendar only needs to store the first element (head) since we are able to access all the other Events through it.

- **Calendar()**
  The default constructor for the Calendar class only needs to set the head to NULL.

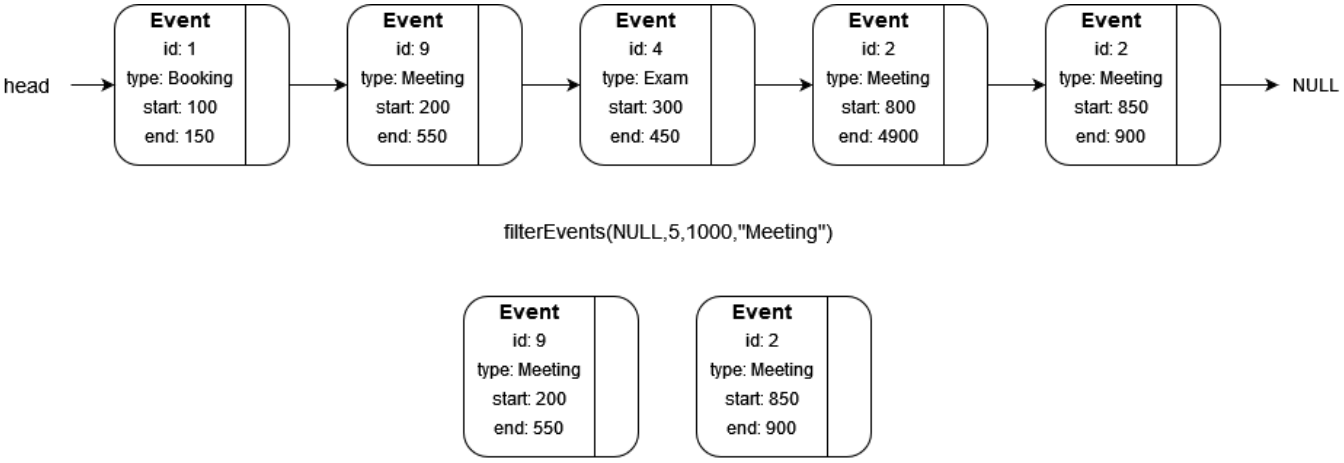
- **Calendar(vector<event_data> input)**
  The overloaded constructor for the Calendar class will be passed a vector of event_data. It first needs to set the head to NULL then it needs to iterate through this vector and call the *createEvent()* function for each item.

- **~Calendar()**
  The destructor will need to call the *clearCalendar()* function.

- **Event* getUpcomingEvent(long int now)**
  This function will need to iterate through your linked list starting at the head to locate the first event whose start time is after the passed now. For example, if the list contains 2 items, the first starting in 1980 and the second starting in 2023. If the passed now is before 1980 (ie 1979) you must return the first element. If the passed now is after 1980 but before 2023 (ie. 2022) you must return the second one.
  If there are no nodes after now you must return NULL. If the list is empty you must return NULL.

- **vector<Event> filterEvents(int* id, long int* start,long int* end, string* type)**
  This function will need to iterate through your linked list starting at the head and filter events according to passed parameters. If a parameter is not set to NULL you must use it as a filter for the events to add. For example, if the type and start parameter are not NULL you must return a vector of every event of that type after the starting time. If all parameters are null you

must return a vector with all the events. If there don't exist any events with those parameters you must return an empty vector.



In the above example, we asked that they filter all that start after 5, end before 1000 and that are Meeting types. Thus only 2 nodes will be added to the vector.
Note: When comparing start and end we compare before and after not at that time. Thus do not use <= and >=. Only use < and >.

- **void alterEvent(int id, long int* end, string* type)**
  This function will need to iterate through your linked list starting at the head and alter the event whose id matches the passed id. You may assume only 1 node with that id will exist. If the end/type parameter is not NULL you must change the events end/type to the new end/type value. Do not delete the event while altering it.

- **void removeEvent(int id)**
  This function will need to iterate through your linked list starting at the head and remove the event of that id.

- **void createEvent(event_data data)**
  This function will receive an event_data object that it uses to create an Event and place it inside our linked list. The list must stay sorted by event start time. If 2 events have the same start time you must place the new event after the old one.

- **void clearCalendar()**
  This function will need to iterate through our entire linked list and delete every event inside it. Ensure that you do not double delete and that you set the Calendar head to NULL. Valgrind will be used to ensure all the Events are deleted properly.

- **Event* getFirstEvent()**
  This function returns the head pointer.

- **friend ostream operator«(ostream out,Calendar calendar)**
  The overloaded « operator will need to place each event as well as a counter into the ostream. Each event will also be newline terminated. The format of your output must be as the following:
  counter: Eventnewline
  Example:

```
0: Testing 1970/01/01 00:00:01->1970/01/01 00:00:02
1: Booking 2022/09/27 14:36:41->2022/12/16 19:52:51
2: Meeting 2023/01/03 20:01:35->2023/02/22 05:53:37
3: Semester Test 2023/02/06 21:53:55->2023/04/12 03:39:16
```

# 5 Submission

You need to submit your source files on the Fitch Fork website (https://ff.cs.up.ac.za/). Only the following files should be in a zip archive named uXXXXXXXX.zip where XXXXXXXX is your student number:

- Utils.h
- Event.h
- Event.cpp
- Calendar.h
- Calendar.cpp

**Ensure that your archive is correct and that your files are not within another folder within the archive.**
Your code should be able to be compiled/executed with the following commands:

- make
- make run
- make clean
- valgrind –leak-check=full ./main

For this practical you are not allowed to use any other includes than the ones provided.

You have 10 submissions and your best mark will be your final mark. Upload your archive to the Practical 7 slot on the Fitch Fork website. **No late submissions will be accepted!**
